HIV INTEGRASE INHIBITORS

BACKGROUND OF THE INVENTION

5

Human immunodeficiency virus (HIV) has been identified as the etiological agent responsible for acquired immune deficiency syndrome (AIDS), a fatal disease characterized by destruction of the immune system and the inability to fight off life threatening opportunistic infections. Recent statistics (UNAIDS: Report on the Global HIV/ AIDS Epidemic, December 10 1998), indicate that as many as 33 million people worldwide are infected with the virus. In addition to the large number of individuals already infected, the virus continues to spread. Estimates from 1998 point to close to 6 million new infections in that year alone. In the same year there were approximately 15 2.5 million deaths associated with HIV and AIDS.

There are currently a number of antiviral drugs available to combat the infection. These drugs can be divided into three classes based on the viral protein they target and their mode of action. In particular, saquinavir, indinavir, ritonavir, nelfinavir and amprenavir are competitive inhibitors of 20 the aspartyl protease expressed by HIV. Zidovudine, didanosine, stavudine, lamivudine, zalcitabine and abacavir are nucleoside reverse transcriptase inhibitors that behave as substrate mimics to halt viral cDNA synthesis. The non-nucleoside reverse transcriptase inhibitors, nevirapine, delaviridine and efavirenz inhibit the synthesis of viral cDNA via a non-competitive (or 25 uncompetitive) mechanism. Used alone these drugs are effective in reducing viral replication. The effect is only temporary as the virus readily develops resistance to all known agents. However, combination therapy has proven very effective at both reducing virus and suppressing the emergence of resistance in a number of patients. In the US, where combination therapy is 30 widely available, the number of HIV-related deaths has declined (Palella, F.

J.; Delany, K. M.; Moorman, A. C.; Loveless, M. O.; Furher, J.; Satten, G. A.; Aschman, D. J.; Holmberg, S. D. *N. Engl. J. Med.* 1998, 338, 853).

Unfortunately, not all patients are responsive and a large number fail this therapy. In fact, approximately 30-50% of patients ultimately fail combination therapy. Treatment failure in most cases is caused by the emergence of viral resistance. Viral resistance in turn is caused by the rapid turnover of HIV-1 during the course of infection combined with a high viral mutation rate. Under these circumstances incomplete viral suppression caused by insufficient drug potency, poor compliance to the complicated drug regiment as well as intrinsic pharmacological barriers to exposure provides fertile ground for resistance to emerge. More disturbing are recent findings which suggest that low-level replication continues even when viral plasma levels have dropped below detectable levels (< 50 copies/ml) (Carpenter, C. C. J.; Cooper, D. A.; Fischl, M. A.; Gatell, J. M.; Gazzard, B. G.; Hammer, S. M.; Hirsch, M. S.; Jacobsen, D. M.; Katzenstein, D. A.; Montaner, J. S. G.; Richman, D. D.; Saag, M. S.; Schechter, M.; Schoolery, R. T.; Thompson, M. A.; Vella, S.; Yeni, P. G.; Volberding, P. A. *JAMA* 2000, 283, 381). Clearly there is a need for new antiviral agents, preferably targeting other viral enzymes to reduce the rate of resistance and suppress viral replication even further.

HIV expresses three enzymes, reverse transcriptase, an aspartyl protease and integrase, all of which are potential antiviral targets for the development of drugs for the treatment of AIDS. However, integrase stands out as being the only viral enzyme not targeted by current therapy. The integrase enzyme is responsible for insertion of the viral cDNA into the host cell genome, which is a critical step in the viral life cycle. There are a number of discrete steps involved in this process including processing of the viral cDNA by removal of two bases from each 3'-terminus and joining of the recessed ends to the host DNA. Studies have shown that in the absence of a

functional integrase enzyme HIV is not infectious. Therefore, an inhibitor of integrase would be useful as a therapy for AIDS and HIV infection.

A number of inhibitors of the enzyme have been reported. These include, nucleotide-based inhibitors, known DNA binders, catechols and hydrazide containing derivatives (Neamati, N. *Expert Opin. Ther. Patents* 2002, 12, 709-724). Diketoamide HIV integrase inhibitors have been disclosed (WO 0316266, WO 0335076, WO 0335077, WO 02070486). However, no clinically approved compound has resulted from these leads. Thus, clinically effective inhibitors of HIV integrase would fulfill a therapeutic need.

15 In the present invention, unless otherwise specified the following definitions apply.

The numbers in the subscript after the symbol "C" define the number of carbon atoms a particular group can contain. For example, "C₁-C₆" means a substituent containing from one to six carbon atoms.

20 As used herein, the term "alkyl" means a saturated, straight chain or branched monovalent hydrocarbon radical having the stated number of carbon atoms. Examples of such alkyl radicals include methyl, ethyl, n-propyl, isopropyl, n-butyl, isobutyl, sec-butyl, t-butyl and, where indicated, higher homologues and isomers such as n-pentyl, n-hexyl, 2-methylpentyl and the like. Haloalkyl refers to an alkyl radical that is substituted with one
25 or more halo radicals, such as trifluoromethyl.

As used herein, the term "cycloalkyl" means a non-aromatic 3-6 membered ring. Examples include, cyclopropyl, cyclobutyl, cyclopentyl and cyclohexyl.

Halo means chloro, bromo, iodo or fluoro.

“Aryl” means an aromatic hydrocarbon having from six to ten carbon atoms; examples include phenyl and naphthyl, indenyl, azulenyl, fluorenyl and anthracenyl.

The term “heterocycle” refers to a monocyclic saturated heterocyclic nuclei having 3-6 atoms containing 1-3 heteroatoms selected from nitrogen, oxygen or sulfur. Heterocycles include, for example, piperidinyl, piperazinyl, pyrrolidinyl and morpholinyl.

“Heteroaryl” means a five- or six-membered aromatic ring containing at least one and up to four non-carbon atoms selected from oxygen, sulfur and nitrogen. Examples of heteroaryl include 2-furyl, 3-furyl, 2-pyridyl, 3-pyridyl, 4-pyridyl, pyrazinyl, 2-thienyl, 3-thienyl, pyrrolyl, oxazolyl, thiazolyl, imidazolyl, pyrazolyl, isoxazolyl, isothiazolyl, 1,2,3-oxadiazolyl, 1,2,3-triazolyl, 1,3,4-thiadiazolyl, pyridazinyl, pyrimidinyl, 1,3,5-triazinyl and 1,3,5-trithianyl.

By virtue of its acidic moiety, where applicable, a compound of Formula I forms salts by the addition of a pharmaceutically acceptable base. Such base addition salts include those derived from inorganic bases which include, for example, alkali metal salts (e.g. sodium and potassium), alkaline earth metal salts (e.g. calcium and magnesium), aluminum salts and ammonium salts. In addition, suitable base addition salts include salts of physiologically acceptable organic bases such as trimethylamine, triethylamine, morpholine, pyridine, piperidine, picoline, dicyclohexylamine, N,N'-dibenzylethylenediamine, 2-hydroxyethylamine, bis-(2-hydroxyethyl)amine, tri-(2-hydroxyethyl)amine, procaine, dibenzylpiperidine, N-benzyl-phenethylamine, dehydroabietylamine, N,N'-bishydroabietylamine, glucamine, N-methylglucamine, collidine, quinine, quinoline, ethylenediamine, ornithine, choline, N,N'-benzylphenethylamine, chlorprocaine, diethanolamine, diethylamine, piperazine, tris(hydroxymethyl)aminomethane and tetramethylammonium hydroxide

and basic amino acids such as lysine, arginine and N-methylglutamine. These salts may be prepared by methods known to those skilled in the art.

Salts of an amine group may also comprise quaternary ammonium salts in which the amino nitrogen carries a suitable organic group such as an
5 alkyl, alkenyl, alkynyl or aryl moiety.

Compounds of Formula I which are substituted with a basic group may exist as salts formed through acid addition. The acid addition salts are formed from a compound of Formula I and a pharmaceutically acceptable inorganic acid, including but not limited to hydrochloric, hydrobromic,
10 hydroiodic, sulfuric, phosphoric, or an organic acid such as p-toluenesulfonic, methanesulfonic, acetic, benzoic, citric, malonic, fumaric, maleic, oxalic, succinic, sulfamic, or tartaric. Thus, examples of such pharmaceutically acceptable salts include chloride, bromide, iodide, sulfate, phosphate, methanesulfonate, citrate, acetate, malonate, fumarate, sulfamate,
15 and tartrate.

Certain compounds of Formula I, and their salts, may also exist in the form of solvates with water, for example hydrates, or with organic solvents such as methanol, ethanol or acetonitrile to form, respectively, a methanolate, ethanolate or acetonitrilate. The present invention includes each solvate and
20 mixtures thereof.

In addition, a compound of Formula I, or its salt or solvate, may exhibit polymorphism. The present invention also encompasses any such polymorphic form.

Certain compounds of Formula I may contain one or more chiral
25 centers and exist in different optically active forms. When compounds of Formula I contain one chiral center, the compounds exist in two enantiomeric forms. The present invention includes both enantiomers and mixtures of enantiomers such as racemic mixtures. The enantiomers may be resolved by methods known to those skilled in the art, for example, by formation of
30 diastereoisomeric salts which may be separated by crystallization, gas-liquid

or liquid chromatography, selective reaction of one enantiomer with an enantiomer-specific reagent. It will be appreciated that where the desired enantiomer is converted into another chemical entity by a separation technique, then an additional step is required to form the desired
5 enantiomeric form. Alternatively, specific enantiomers may be synthesized by asymmetric synthesis using optically active reagents, substrates, catalysts or solvents, or by converting one enantiomer into the other by asymmetric transformation.

Certain compounds of Formula I may also exist in different stable
10 conformational forms which may be separable. Torsional asymmetry due to restricted rotation about an asymmetric single bond, for example because of steric hindrance or ring strain, may permit separation of different conformers. The present invention includes each conformational isomer of compounds of Formula I and mixtures thereof.

15 Certain compounds of Formula I may exist in zwitterionic form and the present invention includes each zwitterionic form of compounds of Formula I and mixtures thereof.

The compounds of this invention can also exist as tautomers; therefore the present invention also includes all tautomeric forms.

20 The compounds of Formula I are useful in the inhibition of HIV integrase, the prevention or treatment of infection by the human immunodeficiency virus and the treatment of consequent pathological conditions such as AIDS or ARC. The treatment involves administering to a patient, in need of such treatment, a compound of Formula I, or a
25 pharmaceutically acceptable salt, solvate or prodrug thereof, or a pharmaceutical composition comprising a pharmaceutical carrier and a therapeutically effective amount of a compound of the present invention, or a pharmaceutically acceptable salt, solvate or prodrug therefor.

Treatment extends to prophylaxis as well as established infections or
30 symptoms. This includes initiating treatment pre- and post-exposure to the

virus. In addition, the present invention can be administered in conjunction with other anti-HIV agents (HIV protease inhibitors, nucleoside reverse transcriptase inhibitors, non-nucleoside reverse transcriptase inhibitors, and HIV-entry inhibitors), immunomodulators, antiinfectives and/or vaccines.

5 The compounds of the present invention are also useful in the preparation and execution of screening assays for antiviral compounds. Further, the compounds of the present invention are useful in establishing or determining the binding site of other antiviral compounds to HIV integrase, for example, by competitive inhibition.

10 The compounds of the present invention may be administered orally, parenterally (including subcutaneous injections, intravenous, intramuscular, intrasternal injection or infusion techniques), by inhalation spray or rectally, in dosage unit formulations containing conventional non-toxic pharmaceutically acceptable carriers, adjuvants and vehicles.

15 This invention also provides a pharmaceutical composition for use in the above described therapeutic method. A pharmaceutical composition of the present invention comprises an effective amount of a compound of Formula I in association with a pharmaceutically acceptable carrier, excipient or diluent.

20 The active ingredient in such formulations comprises from 0.1 percent to 99.9 percent by weight of the formulation. By "pharmaceutically acceptable" it is meant that the carrier, diluent or excipient must be compatible with the other ingredients of the formulation and not deleterious to the recipient thereof.

25 The present pharmaceutical compositions are prepared by known procedures using well known and readily available ingredients. The compositions of this invention may be formulated so as to provide quick, sustained or delayed release of the active ingredient after administration to the patient by employing procedures well known in the art. In making the
30 compositions of the present invention, the active ingredient will usually be

admixed with a carrier, or diluted by a carrier, or enclosed within a carrier which may be in the form of a capsule, sachet, paper or other container.

When the carrier serves as a diluent, it may be a solid, semi-solid or liquid material which acts as a vehicle, excipient or medium for the active

5 ingredient. Thus, the compositions can be in the form of tablets, pills, powders, beadlets, lozenges, sachets, elixirs, suspensions, emulsions, solutions, syrups, aerosols, (as a solid or in a liquid medium), soft and hard gelatin capsules, suppositories, sterile injectable solutions, sterile packaged powders and the like.

10 The compounds can be administered by a variety of routes including oral, rectal, transdermal, subcutaneous, intravenous, intramuscular and intranasal.

When administered orally, these compositions are prepared according to techniques well-known in the art of pharmaceutical formulation. For oral
15 administration, the compound is typically formulated with excipients such as binders, fillers, lubricants, extenders, diluents, disintegration agents and the like as are known in the art.

For parenteral administration, the compound is formulated in pharmaceutically acceptable non-toxic, parenterally-acceptable diluents or
20 solvents, such as mannitol, 1,3-butanediol, water, 5 percent dextrose, Ringer's solution or isotonic sodium chloride solution, or suitable dispersing or wetting and suspending agents, such as sterile, bland, fixed oils, including synthetic mono- or diglycerides, and fatty acids, including oleic acid.

A compound of the present invention, or a salt or solvate thereof, can
25 be formulated in unit dosage formulations comprising a dose between about 0.1 mg and about 1000 mg, or more, according to the particular treatment involved. An example of a unit dosage formulation comprises 5 mg of a compound of the present invention in a 10 mL sterile glass ampoule. Another example of a unit dosage formulation comprises about 10 mg of a

compound of the present invention as a pharmaceutically acceptable salt in 20 mL of isotonic saline contained in a sterile ampoule.

The compounds of the present invention can also be administered to humans in a dosage range of 1 to 100 mg/kg body weight in divided doses.

- 5 One preferred dosage range is 1 to 20 mg/kg body weight orally in divided doses. It will be understood, however, that the specific dose level and frequency of dosage for any particular patient may be varied and will depend upon a variety of factors, including the activity of the specific compound employed, the metabolic stability and length of action of that compound, the
10 route of administration, the age, body weight, general health, sex, diet, mode and time of administration, rate of excretion, drug combination, the severity of the particular condition, and the host undergoing therapy.

- General methods useful for the synthesis of compounds embodied in this invention are shown below. The preparations shown below are
15 disclosed for the purpose of illustration and are not meant to be interpreted as limiting the processes to make the compounds by any other methods. It will be appreciated by those skilled in the art that a number of methods are available for the preparation of the compounds of the present invention as provided by Formula I.

- 20 Formula I compounds can be prepared by processes which include processes known in the chemical art for the production of structurally analogous compounds or by a novel process described herein. A process for the preparation of a compound of Formula I (or a pharmaceutically acceptable salt thereof) and novel intermediates for the manufacture of a
25 compound of Formula I, as defined above, provide further features of the invention and are illustrated by the following procedures in which the meanings of the generic radicals are as defined above, unless otherwise specified. It will be recognized that it may be preferred or necessary to prepare a compound of Formula I in which a functional group is protected

using a conventional protecting group, and then to remove the protecting group to provide the compound of Formula I.

Thus, there is provided a process for preparing a compound of Formula I (or a pharmaceutically acceptable salt thereof) as provided in any of the above descriptions which is selected from any of those described in the examples, including the following.

The compounds of the present invention can be synthesized according to the following schemes. Schemes I-III represent general methods for the synthesis of the compounds. In Scheme I, an appropriately substituted amine, **I-1**, can be acylated under standard amide bond forming conditions to yield **I-3**. Methods for this type of transformation are described, in Jerry March, *Advanced Organic Chemistry*, 3rd edition, John Wiley & Sons, 1985. The acetamide **I-3** can be condensed with dimethyl oxalate in the presence of a base such as NaOMe or LiHMDS. In the final step of the sequence, **I-5** can be treated with an aldehyde, **I-6**, and an amine, **I-7**, to deliver the desired product **I-8**.

Scheme I

Scheme II illustrates an alternative synthesis. In this route, amine **I-1** can be coupled to **II-1** using standard amide bond forming methods. The product of this reaction is **II-2** which can be converted into **I-5** by

methanolysis of the dioxalane ring system and the resulting product carried on to the final product in a manner similar to that in Scheme I. In scheme III, compound II-2 can be synthesized as before, but instead of forming intermediate I-5 it can be converted directly to I-8 according to the equation.

5

Scheme II

10

Scheme III

- 5 In Scheme IV, a substituted benzoic acid derivative can be coupled with amine IV-2 using standard amide bond forming methods to yield IV-3. This intermediate can be reduced to the corresponding benzylic amine, IV-4, which can be coupled to I-2. Intermediate IV-5 can then be condensed with dimethyl oxalate under basic conditions resulting in ketoacid IV-6. The final
- 10 product can be delivered by treating IV-6 with paraformaldehyde and amine I-7 in acetic acid at elevated temperature.

Scheme IV

- 5 In Scheme V, (3,4-dichloro-benzyl)-methylamine, V-1, can be coupled to III-B to yield Compound 37-A. This compound can then be treated with paraformaldehyde and amine I-7 resulting in V-2.

Scheme V

5 In Scheme VI, ketone or aldehyde, VI-1, can be condensed with an alkyl-hydroxylamine, VI-2, to yield the corresponding oxime. This can be then reduced with NaBH₃CN to amine VI-4. It will be appreciated by those skilled in the art that this reduction can be carried out with a number of different reducing agents. Intermediate VI-4 can be coupled with III-B to
10 yield VI-5 which can be taken on to VI-7 by two alternative routes. In one, VI-5 can be first treated with methanol to yield the corresponding methyl ester, VI-6, which can be converted to VI-7 as described previously. In the alternative procedure VI-5 can be treated with paraformaldehyde and I-7 as described in Scheme III.

Scheme VI

- 5 In Scheme VII, amine **VII-2** can be attached to an aldehyde-functionalized polystyrene resin (4-formyl-3-methoxy-phenoxy-methyl functionalized polystyrene), **VII-1**, via reductive amination using methodology well known in the art. This intermediate can be coupled to acid, **III-A** using standard amide bond forming reaction conditions.
- 10 Intermediate **VII-4** can be treated with **I-6** and **I-7** to yield **VII-5**. The final product can be cleaved from the resin under acidic conditions to yield product **VII-6**.

Scheme VII

In Scheme VIII, intermediate carboxylic acid, **VIII-1** can be converted
5 to the corresponding acid chloride, **VIII-2**, under standard conditions. This
compound can then be treated with amine **VIII-3** under basic conditions to
yield amide **VIII-4**. Amide **VIII-4** can be treated with paraformaldehyde and
methylamine to provide the final product, **VIII-5**.

Scheme VIII

- 5 In Scheme IX, compound IX-1 can be synthesized according to the procedure of Heynes R. *et al.* Bull. Soc. Chim. Fr. (1977) 906-910 and reacted with CH_3I or Ac_2O to yield intermediates IX-2 and IX-5 respectively. Saponification or hydrogenolysis of the benzyl ester can provide carboxylic acids IX-3 and IX-6 which can be coupled with I-1 under amide bond forming reaction conditions. In the final step of the synthesis the methyl enol of XI-4 and the acetyl enol of IX-7 can be removed to deliver the final product IX-8.
- 10

Scheme IX

In scheme X, Compound 82-A can be treated with trifluoroacetic acid to effect hydrolysis of the dimethyl-acetal. This then can be reacted with an heterocycle X-1 and a reducing agent such as sodium cyanoborohydride (NaBH₃CN) to yield X-2. It will be understood by those skilled in the art that
 5 alternative reducing agents exist which can be used to carry out the same transformation.

Scheme X

In scheme XI Compound 24 can be reacted with amines, XI-1 and XI-3, using standard amide bond forming reagents to form compounds XI-2 and XI-4 respectively.

Scheme XI

- 5 Another method for the synthesis of compounds of the current invention is illustrated in scheme XII. In this scheme Compound 84-A can be reacted with the corresponding acid chloride XII-1, sulfamoyl chloride XII-3 or sulfonyl chloride XII-5 under basic conditions to deliver compounds XII-2, XII-4 and XII-6 respectively.

Scheme XII

In still another method to synthesize compounds of formula V-2, amine I-7 and paraformaldehyde can be reacted in methanol at elevated temperature to form intermediate XIII-1 as shown in scheme XIII. This

intermediate is not isolated but added to a methanolic solution of Compound 37-A to yield compounds of formula V-2.

Scheme XIII

5

The synthesis of compounds of formula XVI-1 is illustrated in Scheme XIV. In this scheme Compound 93-A can be converted to the corresponding methyl ester, 93-B, as described in the schemes above. Amine I-7 and paraformaldehyde can be condensed to form intermediate XIII-1 which is reacted with 93-B as before to yield XIV-1.

10

Scheme XIV

Compounds of this invention can also be synthesized according to the method illustrated in Scheme XV. In this method 2,4-difluorobenzaldehyde can be treated with thiomethoxide to generate 2-methylthio-4-fluorobenzaldehyde which can be converted to compound XV-1 via reductive amination with amine R^3NH_2 (IV-2). This intermediate in turn can be acylated with III-B to yield XV-2. Oxidation of the sulfide to the corresponding sulfoxide and sulfone can be carried out under conditions familiar to those skilled in the art. Conversion of XV-3 and XV-4 to the corresponding compounds of formulas XV-5 and XV-6 can be achieved by reaction with amine I-7 and paraformaldehyde as described in previous methods.

Scheme XV

In another method Compound 120-B can be treated with I-7 and
5 paraformaldehyde to yield compounds of formula XVI-1, as illustrated in
Scheme XVI.

DESCRIPTION OF SPECIFIC EMBODIMENTS

The specific examples that follow illustrate the syntheses of the compounds of the instant invention, and are not to be construed as limiting the invention in sphere or scope. The methods may be adapted to variations in order to produce compounds embraced by this invention but not specifically disclosed. Further, variations of the methods to produce the same compounds in somewhat different manner will also be evident to one skilled in the art.

In the following experimental procedures, all temperatures are understood to be in Centigrade (C) when not specified. The nuclear magnetic resonance (NMR) spectral characteristics refer to chemical shifts (δ) expressed in parts per million (ppm) versus tetramethylsilane (TMS) as reference standard. The relative area reported for the various shifts in the proton NMR spectral data corresponds to the number of hydrogen atoms of a particular functional type in the molecule. In certain cases where the product is isolated as an inseparable mixture of isomers the integration of protons is given in decimal fractions corresponding to the proportion of that particular isomer's protons in the mixture. The nature of the shifts as to multiplicity is reported as broad singlet (bs or br s), broad doublet (bd or br d), broad triplet (bt or br

t), broad quartet (bq or br q), singlet (s), multiplet (m), doublet (d), quartet (q), triplet (t), doublet of doublet (dd), doublet of triplet (dt), and doublet of quartet (dq). The solvents employed for taking NMR spectra are acetone- d_6 (deuterated acetone), DMSO- d_6 (perdeuterodimethylsulfoxide), D_2O (deuterated water), $CDCl_3$ (deuteriochloroform) and other conventional deuterated solvents.

The abbreviations used herein are conventional abbreviations widely employed in the art. Some of which are: calcd (calculated); DMSO (dimethylsulfoxide); EDC (1-(3-dimethylaminopropyl)-3-ethylcarbodiimide hydrochloride); EtOAc (ethyl acetate); HOBT (1-hydroxybenzotriazole); HPLC (high-pressure liquid chromatography); LC/MS (liquid chromatography, mass spectroscopy); LDA (lithium diisopropyl amide); LiHMDS (lithium bis(trimethylsilyl)amide); MCPBA (3-chloroperoxybenzoic acid) SiO_2 (silica gel); THF (tetrahydrofuran), TFA (trifluoroacetic acid), Me (methyl), Et (ethyl), Ph (phenyl), tBuOK (potassium tert-butoxide), NaOMe (sodium methoxide), NaOEt (sodium ethoxide), Boc (tert-butoxycarbonyl), and DEAD (diethylazo dicarboxylate).

Soc.,(1959) 81, 3725) in a mixture of tetrahydrofuran (20 ml) and 40 % aqueous sodium acetate (10 ml) was cooled to 0-5 °C (ice bath) and treated with a solution of acetyl chloride (0.3 g in tetrahydrofuran) added dropwise over 5 min. After 1 h at 0-5 °C, the reaction
25 mixture was diluted with ethyl acetate, washed successively with 1 N

hydrochloric acid, saturated sodium bicarbonate, brine and dried (magnesium sulfate). EXAMPLE 80

Method for the preparation of compounds 80-724

20

PL-FMP resin (4-formyl-3-methoxy-phenoxyethyl functionalized polystyrene), **VII-1** in Scheme VII or similar aldehyde derivatized resin (approximately 40 mg, 0.048 meq.) was suspended in 2ml of anhydrous DMF, anhydrous trimethylorthoformate and acetic acid mixture in 7:3:1 ratio. To this mixture was added a primary amine, **VII-2** in scheme VII, (0.72 mmol) followed by sodium triacetoxo borohydride (0.72 mmol). The resulting mixture was agitated for 72 h at room temperature using a shaker. The resin was filtered, washed successively with (DMF, THF and DCM, 3 X 2 ml each), dried and used as is in the next step.

25

The resin (**VII-3** in Scheme VII) was suspended in anhydrous dichloromethane (1mL) and to this was added, 2,2-dimethyl-5-(carboxymethylene)-1,3-dioxalan-4-one (Compound III-A) (16.5 mg, 0.096 mmol), Pybop (50 mg, 0.096 mmol) and $i\text{Pr}_2\text{NEt}$ (24.8 mg, 0.192 mmol). The resulting mixture was agitated for 48 h at room temperature using a shaker. Resin was filtered, washed successively (DMF, THF and DCM, 3 X 2 ml each), dried and used in the next step.

Next the resin, **VII-4** in Scheme VII, was suspended in 1ml anhydrous N-methyl-2-pyrrolidinone (NMP). To this mixture was added a preformed imine mixture (preformed by heating aldehyde (18 mg, 0.55 mmol), and amine (0.5mmol) and 0.25 ml methanol, at 70 °C for 2h) and the resulting mixture was heated with agitation in a sealed container at 70-80°C for 72 h. Resin was filtered, washed successively with (DMF, DMF/MeOH (1:1), THF and DCM, 3 X 2 ml each), dried.

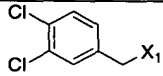

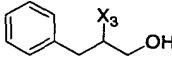

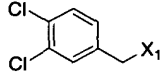

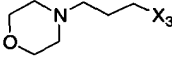

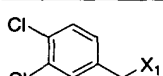

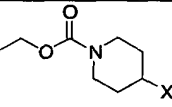

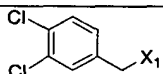

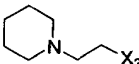

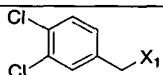

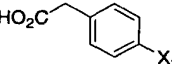

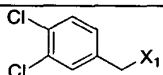

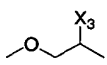

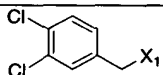

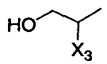

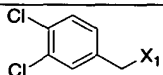

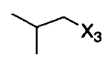

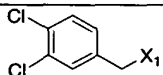

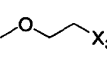

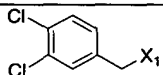

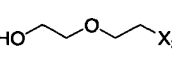

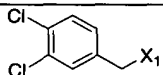

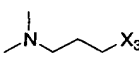

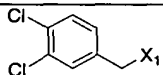

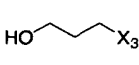

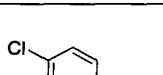

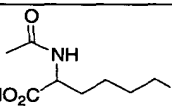

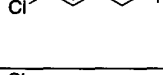

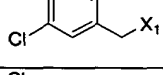

The final product, **VII-6** in Scheme VII, was cleaved from the resin by treating with 1.5 ml of 1:1 mixture of trifluoroacetic acid and dichloromethane for 1 h. TFA solution was filtered and the solvent was evaporated to give the required product.

BIOLOGICAL ACTIVITY

For each reaction, 5 pmole of biotin labeled substrate DNA was bound to 100ug of Streptavidin coated PVT SPA beads (Amersham Pharmacia Biotech). 0.26 ng of recombinant integrase was incubated with the beads for

90 min at 37°C. Unbound enzyme was removed by washing the complex followed by addition of inhibitors and 0.1 fmol of P33 labeled target DNA. Reaction was stopped by adding EDTA to a final concentration of 10 mM. Samples were counted in TopCountNXT (Packard) and the CPM was used as a measure of integration. Reaction condition was as described in A.

Engelman and R. Craigie, J. Virol. 69, 5908-5911 (1995). The sequences of substrate and target DNA were described in Nucleic Acid Research 22, 1121-1122 (1994). Using this assay, representative examples were found to have $IC_{50} = 0.01$ to 50 μ M. The table below shows the percent inhibition of HIV-integrase in the presence of 20 μ M of compounds 1-79.

Inhibition of HIV replication

Cell culture assays were performed using a single cycle, recombinant HIV virus expressing Renella luciferase. Anti-viral activity was evaluated by measuring the production of luciferase in the infected cells 5 days post-infection. Susceptibility of the virus to compounds was determined by incubation in the presence of the serially-diluted compound. The 50% effective concentration (EC₅₀) was calculated by using the exponential form of the median effect equation where $(Fa) = 1/[1 + (ED_{50}/\text{drug conc.})^m]$.

Representative compounds of this invention tested in this assay have EC₅₀'s of approximately 0.01 to 150 μ M.
